⑩ Cardiac assist device.

⑪ A muscle-powered pump to assist the natural heart is disclosed. The device comprises an oblate, spheroidal-shaped pumping chamber (20) surrounded by innervated muscular tissue (22). The device (10) may be coupled to the ventricle and descending aorta with valves (28, 30) and be stimulated in synchrony with the natural depolarization of the heart or the device (12, 14, 16) may be inserted into the descending aorta and used as a counter pulsation device. In this application, the innervated muscle (22) is stimulated after a brief delay from the natural cardiac depolarization.

## CARDIAC ASSIST DEVICE

BACKGROUND OF THE INVENTION

The present invention relates to a totally implantable muscle-powered cardiac assist device to be used as an auxiliary pump in conjunction with the natural heart. In one configuration the device comprises a pair of tubular shunts coupled to the aorta and left ventricle of the heart which communicate with an elastic chamber formed in the shape of an oblate ellipsoid. Valves located within the shunts permit blood to flow from the weak or damaged left ventricle of the heart into the aorta when the elastic chamber is compressed. An alternate configuration involves the use of the elastic chamber as an extra-aortic counterpulsation device with no valve requirement.

The mechanical energy required to compress the chamber is supplied by an innervated autogenous muscle surrounding the elastic chamber. This muscle is stimulated by an implantable pulse generator in synchrony with the ventricular depolarization of the patient's heart. In operation, the contraction of the elastic chamber under the influence of a muscle tissue forces blood into the aorta. Additionally, the pulse generator provides chronic ultra-low frequency stimulation to the muscle tissue to maintain a high population of slow twitch-type muscle fibers.

The use of autogenous muscle to drive mechanical pumps is known in the art from U.S. Patent No. 4,078,267 which discloses an artificial heart propelled by respiratory muscles. Devices of this type have enjoyed only limited success because, mammalian skeletal muscle is not capable of long-term pumping due to metabolic fatigue.

Recently it has been demonstrated that chronic electrical stimulation of muscle tissue produces an adaptive transformation of muscle tissue which increases the capillary density in the muscle tissue as well as the mitochondrial volume and results in an increased work capacity of the transformed muscle. Histologically, such tissue is transformed to the slow twitch-type which exhibits greatly increased resistance to fatigue.

Early experimental evaluation of skeletal muscles for myocardial augmentation was reported by Kantrowitz and McKennon. See Experimental Use of the Diaphragm as an Auxiliary Myocardium, Surgical Forum 9, Page 266, 1959. By wrapping diaphragm muscle around the heart and stimulating it via the phrenic nerve, they observed no significant hemodynamic effects; however, when employed as the counterpulsation device, they noted a short-term increase in the diastolic aortic pressure. Later, in 1964, Nakamora and Glenn utilized the diaphragm to assist atrial function. The diaphragm graft in the atrium continued to contract in response to stimulation from the phrenic nerve and served to elevate the right atrial pressure chronically. See Graft of the Diaphragm as a Functioning Substitute for the Myocardium; an Experimental Study, J Surg Res 4; 435, 1964.

Other approaches which involve the use of small spring-loaded diaphragm pumps with externally positioned flap valves have been energized by canine quadricep femorous muscles. Mechanical pumps of this type have shown outputs of 600-700 milliliters per minute.

These early studies demonstrated the potential for the use of skeletal muscles to augment ventricular action of the heart. However, this initial work indicated that a critical problem existed in the deterioration of muscle performance with continued use. Attempts at improving the hemodynamic behavior of the muscle graft by lower

0216042

frequency stimulation was demonstrated by Doer, et al in 1984. See Synchronously Stimulated Skeletal Muscle Graft for Myocardial Repair, J Thorac Cardiovasc Surg 87: 325, 1984. These more recent studies demonstrated that 5 skeletal muscle, while initially capable of hemodynamic work, fatigues rapidly even under conditions less demanding than those which are tolerated indefinitely by the cardiac muscle itself.

Although skeletal muscles contain populations of 10 fibers which share many of the characteristics of cardiac muscle tissue, the skeletal type (I) or slow twitch fibers serve primarily a postural role in that they are required to sustain prolonged periods of activity without appreciable fatigue. However, in the tissue suitable for 15 application to cardiac assist devices, these fibers are interspersed with at least an equal number of fast or type (II) fibers. These latter fibers have the properties suited to brief periods of intense activity, their fast contractile characteristics derive from specific 20 contractile protein isoforms and extensive sarcotubular system and their dependence on energy derived from anaerobic glycolysis. This metabolic substrate renders the muscles susceptible to fatigue under conditions of prolonged use even at low cardiac rate duty cycles such as 25 those demonstrated by Doer. Additionally, unlike cardiac muscle cells which contract as a syncytium, skeletal muscle fibers are normally recruited to an extent determined by the intensity of activation and in a fixed sequence. In practice, the fast fibers are the first to 30 contract and the slow fibers are the last to contract. This structural property of the skeletal muscles minimizes the functional demand placed upon the fibers which are most susceptible to fatigue. However, the application of such tissues to cardiac assist devices require that all of 35 the muscle tissues be recruited simultaneously and be

equally active with the consequence of chronic fatigue.

Over the past fifteen years, however, a plasticity of muscle fiber type has been demonstrated in response to chronic electrical stimulation. In 1969, Salmons, et al 5 demonstrated that the contractile speed of fast muscles could be modulated to a striking extent by continuous electrical stimulation of the motor nerve at a frequency of 10 Hz.

There is now a large body of evidence to show that 10 fast skeletal muscles can ultimately acquire all of the physiological, biochemical, and ultrastructural characteristics of slow muscle under conditions of chronic stimulation. Such adapted muscles demonstrate a corresponding increase in the use of enzymes for aerobic 15 metabolism and a decrease in the enzymes for glycolysis.

When a change is also involved, the contractile proteins period is reflected by an increased conversion of light to heavy chain isoforms of myosin characteristic of slow muscle tissue. As these changes progress over a 20 period of months, the muscle mass contracts progressively more slowly and is more resistant to fatigue than initially. These recent developments have suggested that appropriately adapted skeletal muscle may be harvested to restore myocardial function through surgical procedures.

25 In the present application, however, chronically stimulated and transformed muscle tissue is utilized to actuate a biological pump implanted within the body and connected to the aorta for assisting a weakened or diseased ventricle in the delivery of blood to body.

30 tissues.

In this context, the present invention is directed to an optimized biological pump which exploits the ability of transformed tissue to augment the ventricular action of the heart. This invention discloses two alternate

embodiments to achieve the desired goal of a totally implantable, body-compatible cardiac assist system.

Brief Description of the Drawings

The figure shows a cross-section of the cardiac 5 assist device of the AACCS system as well as a cross-section of the EABC system.

Detailed Description of the Invention

I. The first embodiment is referred to as a Apico-Aortic Conduit System (AACCS), depicted in the Figure 10 at 10; and, the second embodiment is referred to as an Extra-Aortic Balloon Counterpulsation System (EABC) and is shown in the alternative attachments to the descending aorta at 12, 14 and 16.

In either embodiment, the pump consists of an 15 elastomeric chamber 20, surrounded by a muscle sheath 22, formed from transformed muscle tissue. The chamber is shaped in the form of an oblate ellipsoid having a horizontal axis 26 and a vertical axis 24. In the AACCS system, unidirectional heart valves 28, 30 may be provided 20 to establish the flow direction of blood through the chamber. These valves are located in apertures formed in the periphery of the elastomeric chamber. Valves suitable for this application include the Medtronic mitral heart valve Model 7700 having an orifice diameter of 2 cm for 25 the entry valve 28. A valve suitable for the exit valve 30 of the chamber is the Medtronic aortic heart valve Model A7700 having an orifice diameter of 1.6 cm.

The elastic chamber is shaped in the form of an ellipsoid of revolution. The generating ellipse has a 30 major or horizontal axis 26, which is the axis of revolution and a minor or vertical axis 24 as shown in the Figure. For a desired fluid stroke volume of 70 cc,

the chamber should have a volume of approximately 140 cc. This is based upon an assumed ejection ratio of 50%. For a volume of 140 cc, the dimensions of the major and minor axes are related by  $b = 5.78/\sqrt{a}$ .

5 To compute the minimum force required to pump the desired stroke volume, one may model the chamber as an equivalent cylinder, having a volume equal to the chamber, whose length is equal to the horizontal axis of the ellipse. In this instance, the cylinder will have a base 10 radius  $\bar{b}$  given by  $\bar{b} = 4.72/\sqrt{a}$ . The force required to displace the desired blood volume is given by:

$$(70/\gamma\bar{b})^2 (\rho/\gamma) = 602.95a$$

where  $\gamma$  is the ejection time (0.35 sec) and  $\rho$  is the specific gravity of blood (1.055). This force corresponds 15 to the end pressure or terminal pressure,  $P_{ter}$ , in the chamber distributed over the exit aperture of the chamber as determined by the size of the aortic valve aperture,  $r_0$ .

In practice, sufficient muscle mass is wrapped around 20 the balloon to generate a static pressure of 120 mm of mercury or  $1.6 \times 10^5$  dynes per square centimeter within the chamber. This is the available pressure,  $P_{av}$ , responsible for driving blood into the body systemic vessels.

25 The mass flow rate for a Newtonian fluid in the laminar regime is given by Poiseuille expression  $f = \frac{\pi P r^4}{8L\eta}$ , where  $P$  is the pressure,  $L$  is the length of the tube,  $r$  is the tube radius, and  $\eta$  is the viscosity 30 coefficient. As previously mentioned, the available pressure responsible for driving the fluid out of the pump is related to the radius of the aortic valve as indicated by the relationship above. Likewise, the minimum pressure or terminal pressure in the chamber is related to the 35 average radius of the balloon which is taken as the radius

of the equivalent cylinder. The quantity  $P_r^4$  in the Poiseuille relation gives an estimate of the system compliance, and therefore, to achieve maximum compliance matching, we should have

5  $P_{av1} \times r^4 = P_{ter} \times (\pi)^4$ . This leads to: a  $r_o^6 = 0.595$ . For an aortic valve orifice,  $r_o$ , of 0.8 cm, we have a = 2.27 cm and b = 3.84 cm for the desired dimensions of the oblate ellipsoid.

Optimization of the chamber size is based on a fluid 10 flow rate, f, expressed in cc's per second, which is equal to the systolic's cardiac output of the cardiac assist device. The parameters should be optimized to provide a stroke volume of 70 cc, an ejection time of 350 ms and a volume flow rate of 200 cc per second. The fluid velocity 15 is given by the flow rate divided by the cross-sectional area, A. Therefore, the average flow velocity during systolic time,  $\bar{V} = f/A = 2.86a$ . At the end of the ejection time, the fluid flow velocity within the chamber must become zero.

20 With respect to the muscle mass 22 required in this cardiac assist device, one can use Young-LaPlace equation to compute the tension required at the wall of the chamber to generate the 120 mm of mercury pressure. For a cylindrical balloon of unit radius, the wall tension is 25 computed to be  $1.6 \times 10^5$  dyne per centimeter.

Measurements of muscle fibers reveal that the isometric force generated by a tensed muscle is approximately  $2.9 \times 10^3$  grams per square centimeter of muscle cross-section or  $2.9 \times 10^6$  dynes per square centimeter of muscle cross 30 section. See Casey, E.J.; "Biophysics, Concepts and Mechanisms," Reinhold Books, New York, 1962, p 293.

Calculations for a cylindrical balloon of unit radius ( $R = 1$  cm) and sufficient length to accommodate at least

70 ml of blood leads to the following two useful rules of thumb:

Rule 1:  $M = 2 \times 10^{-3} R P$

Where M is the muscular mass in grams, R is the balloon or bladder radius in cm, and P is the balloon pressure in dynes/cm<sup>2</sup>.

Rule 2:  $r_0^6 R^{-2} P = 4 \times 10^3$

where  $r_0$  is the radius of the tube connecting the balloon to the aorta.

10 For example, in order to achieve the human systolic pressure of 120 mm Hg ( $1.6 \times 10^5$  dynes/cm<sup>2</sup>) in a 70 ml balloon of radius  $R = 1$  cm, the required muscle mass is about 320 gm (11.3 oz.) according to Rule 1. Also, the radius,  $r_0$  of the aortic valve, is estimated as 0.5 cm

15 (0.2 inch from Rule 2).

By imposing an  $r_0$  value of 0.8 cm and ejection ratio of 50% on the design parameters, it can be shown that the muscle mass required to wrap around the two caps of the oblate ellipsoid of volume 140 cm<sup>3</sup> is approximately twice that required for a volume of 70 cm<sup>3</sup>, i.e., 645 gm (23 oz.).

### II--The Extra-Aortic Balloon Counterpulsation Pump (EABC)

The pumping chamber here needs no entrance or exit valves as shown in the Figure at 12, 14 and 16. The EABC 25 chamber is connected directly to the divided left subclavian artery distal to the thoracodorsal and thoracoacromial branches. A series (T-connection) 14 or parallel (U-connection) 12, 16 pump can be used. The T-connection is shown in the Figure. The balloon can 30 either be wrapped by the rectus abdominus and latissimus dorsi pedicles, or placed deep to the pectoralis major.

The powering muscle would be stimulated directly by two wire electrodes 32. The stimulator is triggered from the left ventricular electrocardiogram via lead 34 or from

the arterial pressure tracing output. Unlike the AACs, in this embodiment the pump would be triggered at the end diastolic phase of the cardiac cycle. This allows increased muscle perfusion which occurs while the muscle 5 is relaxed during systole. Thus, fatigue can be considerably minimized, not only by this operational mode, but also by using the optimal stimulation parameters and protocol as with the AACs.

In addition, the hemodynamic requirements for the 10 EABC device are minimal. There are no valve requirements and the balloon volume can be chosen commensurate with the severity of the situation. A balloon volume of 30 to 70 cc is recommended with an optimum size of 50 cc. The only requirement is that the balloon shape be spherical or 15 nearly spherical in order to avoid sharp edges and corners where blood may stagnate.

The EABC system can be made to offset the primary or essential hypertension. This type of high blood pressure is caused by the progressive increase in construction of 20 arteries and arterioles and their decreasing compliance, a phenomena which gradually increases with age. This is to be distinguished from malignant hypertension which arises from hormonal disturbances of the adrenal glands that sit atop of the kidneys or from malfunctioning of the 25 baroreceptors of the carotid sinus which is in the back of the neck.

By adjusting the pressure wave on the extra-aortic balloon, one can augment the systolic pressure by decreasing the diastolic pressure level. Notice that 30 infants average 80/46 in blood pressure at birth which rises to 100/60 during the first ten days, and levels up at 120/70 during adulthood. The following increase seems to be gradual reaching 135/80 in the fifties and 150/85 in the seventies. The borderlines of 160/95 are at best 35 empirical in the sense that they represent a gradual

process, and a 50 year-old subject with 160/90 blood pressure is the equivalent of a healthy counterpart who was 135/80 in his fifties and would extrapolate to 160/90 at 90 or 100 years. The invention disclosed herein 5 involves the gradual augmentation of the cardiac output in such a way to compliantly meet this progressive imbalance--with no extra demand from the heart muscle itself.

The pulse generator 36 of the present device must be 10 adapted to provide chronic background stimulation to the innervated autogenous muscle tissue to provide for the maintenance of a high type two fiber population.

To provide for optimization of the stimulation parameters for any given individual it is required that 15 the pulse generator be capable of providing burst stimulation with a burst duration between 150 and 500 milliseconds, with a number of pulses in a burst being less than or equal to 20. The pacemaker should also be capable of providing stimulation pulses at a rate between 20 0 and 150 beats-per-minute with a pulse width duration of between 150 and 500 microseconds. To provide for adjustable thresholds of the autogenous tissue, it is desirable to have an amplitude adjustable within the range of 0 to 15 volts with constant current output. The device 25 must have an R-wave synchronous or triggered operating mode for stimulating the autogenous muscle in phase with the depolarization of the cardiac tissue for use in configuration 10. The delay from ventricular sense to stimulus should be variable between 20 and 500 30 milliseconds and be programmable by the attending physician.

It may also be desirable to provide for stimulating the autogenous tissue at a rate proportional to the sinus rhythm of the patient.

35 What is claimed is:

- 1        1. A cardiac assist device for pumping blood from  
2 the left ventricle to the aorta of a patient's heart in  
3 synchrony with the ventricular depolarization of the  
4 patient's heart comprising:  
5              a first tubular shunt having a proximal and  
6              distal end for connection to said left ventricle  
7              of said heart through said proximal end;
- 8              a second tubular shunt having a proximal and  
9              distal end for connection to said aorta of said  
10          heart;
- 11          \* an elastic pumping chamber having an oblate  
12          ellipsoidal shape defined by a horizontal axis  
13          and a vertical axis adapted to be substantially  
14          completely surrounded by a sheath of innervated  
15          autogenous muscle tissue, and having first and  
16          second annular apertures located at the  
17          periphery of said chamber concentric with said  
18          horizontal axis;
- 19          \* a unidirectional aortic valve coupled to said  
20          distal end of said first tubular shunt and  
21          coupled to said first aperture;
- 22          \* a unidirectional mitral valve coupled to said  
23          distal end of second tubular shunt and coupled  
24          to said second aperture;
- 25          \* a pulse generator adapted to be coupled to a  
26          first and a second electrode for providing low  
27          amplitude continuous stimulation pulses at a low  
28          frequency rate and for providing high amplitude

29            stimulation pulses in synchrony with the  
30            detected depolarization of said ventricle;

31            \* wherein said first electrode is adapted to be  
32            coupled to said autogenous muscle tissue for  
33            stimulation and adapted to be coupled to said  
34            pulse generator; and

35            \* wherein said second electrode is adapted to be  
36            coupled to said ventricle for sensing  
37            depolarizations of ventricular tissues.

1            2. The device of claim 1 wherein said chamber has a  
2 volume between 100 and 200 ml and most preferably 140 ml.

1            3. The device of claim 1 or claim 2 wherein said  
2 first tubular shunt has an internal diameter between 1.5  
3 cm and 2.5 cm.

1            4. The device of claim 1 or claim 2 wherein said  
2 second tubular shunt has an internal diameter between 1.1  
3 cm and 2.1 cm.

1            5. The device of claim 1 or claim 2 wherein the  
2 length of the vertical minor axis (b) and horizontal axis  
3 (a) bear the relationship:

4             $b/\sqrt{a} = 5.78/a^{1/2}$

1        6. The device of claim 1 wherein the muscle mass,  
2 m, required to wrap said chamber is between 350 to 600 gm  
3 and most preferably 560 gm.

1        7. The device of claim 1 further including a  
2 battery-powered stimulator delivering square waves with  
3 programmable delay, frequency, pulse width, pulse train  
4 duration, and current.

1        8. The device of claim 7 wherein the stimulator has  
2 a pulse train duration which varies between 150 and 250  
3 milliseconds with a preferred duration of 200  
4 milliseconds.

1        9. The device of claim 7 wherein the stimulator  
2 pulse width varies between 200 and 300 microseconds with a  
3 preferred value of 250 microseconds.

1        10. The device of claim 7 wherein the stimulator  
2 pulse frequency varies between 20 and 50 Hz (pulses per  
3 second), with a preferred frequency of 35 Hz.

1        11. The device of claim 7 wherein the stimulator  
2 provides a low pulse frequency of 2 to 10 Hz can be  
3 generated for prolonged muscle preconditioning prior to  
4 tetanic activation.

1        12. A cardiac assist device for augmenting blood  
2 flow from the left ventricle to the aorta in synchrony

3 with the ventricular repolarization of the patient's heart  
4 comprising:

- 5        •    an elastic spherical pumping chamber surrounded  
6              by a sheath of innervated autogenous muscle  
7              tissue;
- 8        •    a T-connection of said chamber to the transected  
9              aorta;
- 10       •    a pulse generator adapted to be coupled to a  
11              first and second electrode;
- 12       •    wherein said first electrode is adapted to be  
13              coupled to said autogenous muscle tissue for  
14              stimulation and adapted to be coupled to said  
15              pulse generator; and
- 16       •    wherein said second electrode is adapted to be  
17              coupled to said ventricle for sensing end  
18              repolarizations of ventricular tissues.

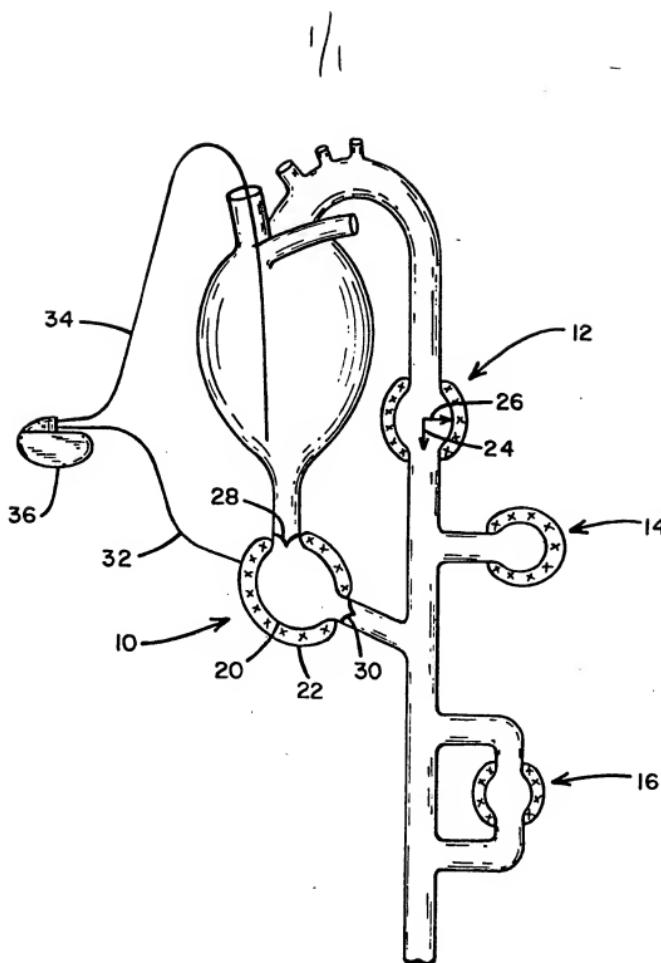

1       13. A cardiac assist device for augmenting blood flow  
2 from the left ventricle to the aorta in synchrony with the  
3 ventricular repolarization of the patient's heart  
4 comprising:

- 5        •    an elastic spherical pumping chamber surrounded  
6              by a sheath of innervated autogenous muscle  
7              tissue;
- 8        •    a T-connection of said chamber to the transected  
9              aorta;

- 10        \*     an alternative U-connection of said chamber to  
11                          the descending aorta;
- 12        \*     a pulse generator adapted to be coupled to a  
13                          first and second electrode;
- 14        \*     wherein said first electrode is adapted to be  
15                          coupled to said autogenous muscle tissue for  
16                          stimulation and adapted to be coupled to said  
17                          pulse generator; and
- 18        \*     wherein said second electrode is adapted to be  
19                          coupled to said ventricle for sensing end  
20                          repolarizations of ventricular tissues.

1        14. The device of claim 12 or claim 13 wherein said  
2 chamber has a volume between 30 and 70 ml and most  
3 preferably 50 ml.

1        15. The device of claim 12 or claim 13 wherein the  
2 counterpulsations are used to offset the primary or  
3 essential hypertension.
